# **Heston Model Definition**

Assume that the spot asset at time t follows the diffusion

$$dS(t) = \mu S(t)dt + \sqrt{v(t)}S(t)dZ_1(t), \tag{1}$$

$$dv(t) = \left(\delta^2 - 2\beta v(t)\right)dt + 2\delta\sqrt{v(t)}dZ_2(t),\tag{2}$$

where  $Z_1$ ,  $Z_2$  are the correlated Wiener processes with  $dZ_1dZ_2=
ho dt$ .

Broadie-Kaya Simulation Method

Andersen Simulation Method

Computation Examples

## **Statistical Estimation**

#### Lemma 1

Let  $X_1, X_2, \ldots, X_n$  be a series of independent and identically distributed random variables, and  $h : \mathbb{R} \to \mathbb{R}$  be a borel function. Then  $h(X_1), h(X_2), \ldots, h(X_n)$  is a series of independent and identically distributed random variables.

Thus, we could write the unbiased consistent estimator of  $\mathbb{E}[h(X)]$  as follows:

$$\widehat{\mathbb{E}[h(X)]} = \frac{1}{n} \sum_{i=1}^{n} h(X_i). \tag{3}$$

## Random and Pseudo-Random Numbers

#### **Definition 2**

A random sequence of numbers is a sequence (in time or in space) with no discernable pattern.

### **Definition 3**

Pseudorandom number generator is an algorithm that generates a sequence of numbers that has no internal pattern. However, the series requires a starting seed, and if the algorithm is started repeatedly with the same seed, it will go through precisely the same sequence of numbers.

Check out the lecture by A.N.Shiryaev (Probability Theory Department  $\times$  Vega Institute Foundation Seminar, Oct 19) for more details.

# **Law of Large Numbers**

## Theorem 4 (Khinchin)

Let  $X_1, X_2, \ldots, X_n$  be a sequence of independent and identically distributed random variables with  $\mathbb{E} X_i = \mu$ . Then

$$\mathbb{P}-\lim_{n\to\infty}\frac{1}{n}\sum_{i=1}^{n}X_{i}=\mu.$$
 (4)

# Theorem 5 (Kolmogorov)

Let  $X_1, X_2, \ldots, X_n$  be a sequence of independent and identically distributed random variables. Then  $\exists \mathbb{E} X_i = \mu$ , if and only if

$$\lim_{n\to\infty}\frac{1}{n}\sum_{i=1}^{n}X_{i}\stackrel{a.s.}{=}\mu.$$
 (5)

## **Central Limit Theorem**

# Theorem 6 (Lindeberg-Lévy)

Let  $X_1, \ldots, X_n$  be a sequence of i.i.d. random variables with  $\mathbb{E}[X_i] = \mu$  and  $\operatorname{var}[X_i] = \sigma^2$ . Then as n approaches infinity, the random variables  $\sqrt{n}(\bar{X}_n - \mu)$  converge in law to a normal distribution  $\mathcal{N}(0, \sigma^2)$ , i.e.

$$\sqrt{n}\left(\bar{X}_n - \mu\right) \xrightarrow{d} \mathcal{N}\left(0, \sigma^2\right).$$
 (6)

### NB

Law of large numbers is a corollarary of the central limit theorem.

## **Monte Carlo Simulation**

#### **Definition 7**

Monte Carlo simulation is a set of techniques that use pseudo-random number generators to solve problems that might be too complicated to be solved analytically. It is based on the central limit theorem.

Asymptotic confidence interval for  $\hat{\mu} = \widehat{\mathbb{E}\left[X\right]}$  at the confidence level  $\alpha$ :

$$\mu \in \left(\hat{\mu} - z_{\alpha/2}\sqrt{\frac{\sigma^2}{n}}, \hat{\mu} + z_{\alpha/2}\sqrt{\frac{\sigma^2}{n}}\right).$$
 (7)

That means that  $LTE = 2z_{\alpha/2}\sqrt{\frac{\sigma^2}{n}}$ .

Introduction to Monte-Carlo Methods

**Euler Simulation Method** 

Broadie-Kaya Simulation Method

Andersen Simulation Method

Computation Example:

## **Forward Euler Scheme for ODEs**

Definition

Suppose that we have an ODE of the form

$$dX(t) = f(X(t), t)dt, \quad X(0) = X_0.$$
 (8)

Then it could be numerically solved by the following finite difference scheme:

$$X_{n+1} = X_n + f(t_n, X_n)h_n,$$
 (9)

where  $t_n = \sum_{k=0}^n h_n$  is a mesh grid.

## **Forward Euler Scheme for ODEs**

V

Global truncation error

#### Lemma 8

Let the solution of (8) have an M-bounded second derivative and let f be L-Lipshitz continious in its second argument. Then the global truncation error of the mesh solution (9) is

$$|X(T) - X_N| \le \frac{hM}{2L} \left( e^{LT} - 1 \right) = O(h).$$
 (10)

# **Euler-Maruyama Scheme for SDEs**

Definition

Suppose we have a diffusion of the form

$$dX(t) = f(X(t), t)dt + \sigma(X(t), t)dW(t), \quad X_0 = X_0.$$

Then it could be numerically solved by the following finite difference scheme:

$$X_{n+1} = X_n + f(t_n, X_n)h_n + \sigma(t_n, X_n)\sqrt{h_n}Z_n,$$
 (11)

where  $(Z_n)_{n=1,2,...}$  is a sample of standard normal random variables, and  $t_n=\sum_{k=0}^n h_n$  is a mesh grid. The same method could be generalized for the two-factor Gaussian diffusions.

# **Euler-Maruyama Scheme for SDEs**

Global truncation error analogue – strong and weak convergence

### **Definition 9**

Let  $\hat{X}^n(t)$  be a piecewise mesh approximation of an SDE solution X(t) (we assume that there exists a unique strong solution). Then a scheme is said to have a strong convergence of order p if

$$\left|\hat{X}^n(t) - X(t)\right| \le C\left(\frac{h}{n}\right)^p, \quad n \to \infty.$$
 (12)

A scheme is said to have a weak convergence of order p if

$$\left|\hat{X}^n(t) - X(t)\right| \le C\left(\frac{h}{n}\right)^p + \frac{C}{n^p}, \quad n \to \infty.$$
 (13)

# **Euler-Maruyama Scheme for SDEs**

Global truncation error – strong and weak convergence

#### Theorem 10

Under some technical assumptions the Euler-Maruyama scheme (11) has a strong convergence of order 1 and a weak convergence of order 1/2.

## **Euler Scheme for the Heston Model**

V

Classical Euler-Maruyama Scheme

Suppose we have the Heston model (1) - (2). Then it could be numerically solved by the following finite difference scheme:

$$S_{n+1} = S_n + \mu S_n h_n + \sqrt{\nu_n} S_n \sqrt{h_n} Z_{1,n},$$
 (14)

$$v_{n+1} = v_n + \left(\delta^2 - 2\beta v_n\right) h_n + 2\delta \sqrt{v_n} \sqrt{h_n} Z_{2,n},\tag{15}$$

where  $(Z_{1,n})_{n=1,2,...}$  and  $(Z_{2,n})_{n=1,2,...}$  are  $\rho$ -correlated samples of standard normal random variables, and  $t_n = \sum_{k=0}^n h_n$  is a mesh grid.

## **Euler Scheme for the Heston Model**

Modified Euler-Maruyama Scheme

But we have a problem: during simulation of the Heston model using Euler method  $S_{t_n}$  and  $v_{t_n}$  could be negative. How do we deal with this inconvenience? Let us introduce the log-prices

$$X(t) := \log \frac{S(t)}{S(0)}.\tag{16}$$

# **Euler Scheme for the Heston Model**

V

Modified Euler-Maruyama Scheme

We take the positive part of the variance:

$$X_{n+1} = X_n + (\mu - 0.5\nu_n^+)h_n + \sqrt{\nu_n^+}X_n\sqrt{h_n}Z_{1,n},$$
(17)

$$v_{n+1} = v_n + \left(\delta^2 - 2\beta v_n^+\right) h_n + 2\delta \sqrt{v_n^+} \sqrt{h_n} Z_{2,n},$$
 (18)

However, the scheme is not accurate, since we ignore the  $dZ_idZ_j$  terms in the Itô-Taylor expansion

### **Conclusion**

We introduced the three most common simulation methods for dynamics of the two-factor Gaussian diffusion model:

- 1. Euler scheme;
- 2. Broadie-Kaya scheme;
- 3. Andersen scheme.

Using these methods we simulated the dynamics of the Heston model and computed the price of the European call options with different strikes and maturities.
